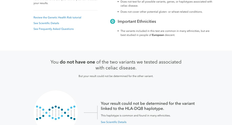
Print

Celiac Disease

Celiac disease is an autoimmune disease that occurs in genetically predisposed people of all ages. Exposure to gluten in wheat, barley, and rye can result in damage to the small intestine. Celiac disease can lead to both digestive and non-digestive problems. The best way to prevent symptoms associated with celiac disease is to avoid consuming gluten.

Basic, you **do not have** one of the two genetic variants we tested.

Your result could not be determined for the other variant.



The test may not be able to determine a result for every variant tested. This can be caused by random test error or other factors that interfere with the test.

How To Use This Test

The last item in dispute: celiac disease or soy sensitivity

Please talk to a medical professional about celiac disease conditions (such as gluten sensitivity, soy allergy, or lactose intolerance) that run in your family.

See Scientific Details
See Frequently Asked Questions

Intended Uses

- Tests the variants near the HLA-DQA1 and HLA-DQB1 genes linked to the **HLA-DQ2.5** and **HLA-DQB1** haplotypes. These haplotypes are associated with celiac disease.

Limitations

- Does not test for all possible variants.
- Does not test for all possible genes.
- Does not test for all possible causes of symptoms, genes, or haplotypes associated with celiac disease.
- Does not cover other autoimmune genes or other related conditions.

Important Information

- For research purposes only. Not for use in clinical practice.
- Test results are available in the **European** dataset.

You **do not have one** of the two variants we tested associated with celiac disease.

But you must watch symptoms associated with the condition.

Your result could not be determined for the variant linked to the HLA-DQB haplotype.

This haplotype is also associated with celiac disease.

See Scientific Details

There is still a chance of developing celiac disease.

About 1 in 100 people in Western countries have celiac disease in the general population.[1] Lifestyle and genetic factors not covered by this test also affect your chances of developing celiac disease.

See Scientific Details

Lifestyle and other factors can also influence the chances of developing celiac disease.

Consult with a healthcare professional before making any major lifestyle changes.

Gluten found in wheat, barley, and rye's proteins can trigger an immune response that damages the small intestine. Some people with increased genetic risk...

About Celiac Disease

Also known as: Coeliac disease, celiac sprue, (1) gluten sensitive enteropathy, nontropical sprue

When it develops

Celiac disease can develop at anytime from infancy to adulthood. Most cases are diagnosed in people in their 30's or 40's. It presents with celiac disease symptoms once other environmental factors trigger it.

How common is the condition?

Celiac disease affects about 1 percent of all Americans. About 1 in 100 people in Western countries have celiac disease.[1]

Typical signs and symptoms

- Anemia, gas, and bloating
- Poor appetite
- Skin rashes
- Fatigue
- Diarrhea
- Weight loss

How to treat it

Celiac disease can be effectively treated by removing all gluten from your diet. This includes foods that are not directly made with wheat, barley, and rye.

Scientific Details

Celiac disease is an autoimmune condition in which the consumption of gluten (found in wheat, barley, and rye) damages the small intestine. This can lead to digestive and non-digestive problems. This test includes two common variants associated with an increased risk of developing the condition.

Celiac disease is associated with the HLA-DQ2.5 and HLA-DQB haplotypes.

These haplotypes are associated with variants in the HLA-DQA1 and HLA-DQB1 genes.

The HLA gene family contains instructions for making a group of proteins called the human leukocyte antigen (HLA) complex. The HLA-DQA1 gene provides instructions for making one part of the HLA-DQ protein. This protein is found on the surface of immune cells. The other half of the protein is produced made by the HLA-DQB1 gene. This protein complex presents foreign peptides to the immune system. Variants in the HLA-DQA1 and HLA-DQB1 genes that result in the HLA-DQ2.5 gene can trigger an inappropriate immune response to gluten.

Read more at Genetics Home Reference[5]

You do not have one of the two genetic variants we tested. Your result for the other tested variant could not be determined.

Security Detected

View All Tested Markers

Marker Tested	Your Genotype*		Additional Information
HLA-DQ2.5 Marker rs2187668	C/C	Typical copy from your mother Typical copy from your other parent	• Biological explanation • Typical vs. variant DNA sequence(s) • Percent of Europeans with common trait variant • References [1], [2], [3], [4], [5], [6], [7], [8]
HLA-DQB Marker rs7454108	**Not determined**		• Biological explanation • Typical vs. variant DNA sequence(s) • References [3], [4], [5], [6], [7], [8], [9], [10]

*The most common allele and what you have are typically called genotypes. The test also cannot detect other mutations, variants, or deletions, and cannot determine if multiple variants are on the same chromosome.

Security Detected is a graphical depiction of the variations detected at the tested genotypes. Each genotype is represented by a pair of letters.

Test Interpretation

Risk Assessment

- The HLA-DQA1 and HLA-DQB haplotypes included in this test are common in many ethnicities. About 15% to 30% of the general population have either or both of these haplotypes.
- Most people with the haplotypes detected by this test do not develop celiac disease. Studies estimate that only 2% of people with one or more copies of the HLA-DQ2.5 or HLA-DQB haplotypes develop celiac disease.[6]
- Having people who develop celiac disease, about 90% have one or more copies of the HLA-DQ2.5 haplotype and about 5% have one or more copies of the HLA-DQB haplotype. The remaining people with celiac disease have partial copies of both.
- People without either of the two tested genotypes are not likely at risk of developing celiac disease.

Health Risk Estimates

Risk estimates are based on the health studies that identify an association between a genetic variant and a health condition.

Consider talking to a healthcare professional if you have any concerns about your results.

References [1], [6]

Other Factors

Other factors besides the variants included in this test can influence your chances of developing celiac disease.

Other factors	References
Gluten Individuals with a genetic predisposition for celiac disease, consuming gluten (found in wheat, barley, and rye) can damage the small intestine and affect the lining of the small intestines. This damages the surface of the small intestine, such as the villi and microvilli. This can lead to a wide range of digestive and non-digestive issues in both digestive and non-digestive symptoms. However, most people with a genetic predisposition never experience any problems from eating gluten.	[20]
Family history Parents, siblings, and children of a person diagnosed with celiac disease have a higher chance of developing the condition themselves. The may primarily be because of genetics, but it can also be because they share a household and eat many common foods. For a person with unknown genetic risk and an affected first-degree relative, the chance of developing celiac disease is about 10-20%, compared to 1% for the general population.	[6], [21]
Other conditions Individuals with health conditions are more likely to develop celiac disease. These conditions include autoimmune disorders (such as Type 1 diabetes, autoimmune thyroiditis, and psoriasis), and to approximately 5% for people with other autoimmune conditions. Down syndrome and Turner syndrome are also linked to celiac disease. It is compared to the 1% prevalence of celiac disease in the general population.	[1], [4], [6]
Sex Some studies have shown that women are more likely to be diagnosed with celiac disease than men. However, this may be because of differences in symptoms between women. Scientists are still trying to figure out if there truly is a difference in risk between the two sexes.	[4], [6]
Other genes There are other genes and variants that have been associated with celiac disease. However, many of these variants may have only a small effect on risk.	

Test Details

Indications for Use

The 23andMe PGS Genetic Health Risk Report for Celiac Disease is indicated for reporting of an individual's genetic risk for Celiac Disease. The report is based on variants in the HLA-DQA1 and HLA-DQB1 haplotypes. The report is designed to identify individuals that are associated with a 5 fold or higher risk of developing celiac disease, but it does not describe a person's overall risk of developing celiac disease. This report is not meant for diagnostic purposes.

Special Considerations

Genetic testing for celiac disease is recommended under certain circumstances by several health professional organizations, including the American College of Gastroenterology.

Clinical Performance

About 95% of all cases of celiac disease are associated with the HLA-DQ2.5 and HLA-DQB haplotypes.

Analytical Performance

Accuracy was determined by comparing results from this test with results from sequencing. All test results were concordant. Call rate was greater than 99%. Reproducibility was greater than 99% between results. For more details on the analytical performance of this test, refer to the package insert.

Warnings and Limitations

- This test does not cover all variants that may cause celiac disease.
- Test results are not diagnostic any health conditions.
- Some results will need further professional for any medical purposes.
- If you are concerned about your results, consult with a healthcare professional.

See the Package Insert for more details on use and performance of the test.

* Sensitivity and Specificity of 23andMe data may vary by race, ethnicity, and ancestry. Sensitivity and specificity are lower in individuals of non-European ancestry due to the smaller number of individuals in the reference dataset.

Celiac Disease

Frequently Asked Questions

Celiac disease is an autoimmune condition in which the consumption of gluten (found in wheat, barley, and rye) damages the small intestine. This can lead to digestive and non-digestive problems. This list includes two common variants associated with an increased risk of developing the condition.

Celiac Disease

What is celiac disease and how is it different from non-celiac disease gluten sensitivity?

Celiac disease is an autoimmune condition in which the consumption of gluten (found in wheat, barley, and rye) can result in damage to the small intestine. The damage occurs because the body has an inappropriate immune reaction to gluten and attacks its own tissues. Non-celiac gluten sensitivity is a condition that is not well understood by scientists.

Other types of celiac disease conditions, such as wheat allergy and gluten ataxia, have been described. Although people with these conditions have reported symptoms similar to those with celiac disease, the symptoms are thought to be different. Like celiac disease, these conditions can be triggered by the consumption of gluten. Consult with a healthcare-related condition, talking to a healthcare provider may help determine if more testing is appropriate.

You can learn more about celiac disease from the following resources:

- Celiac Disease Foundation[1]
- National Celiac Association[2]
- Beyond Celiac[3]
- Association of European Coeliac Societies[4]

Is this answer helpful? Yes No

What does this test do?

This test looks for two specific genetic variants, one in the HLA-DQA1 gene and one near the HLA-DQB1 gene. These genes are part of the HLA-DQ2.5 and HLA-DQB haplotypes. These haplotypes are associated with celiac disease.

People with the HLA-DQ2.5 and HLA-DQB haplotypes are more likely to develop celiac disease. However, most people with these haplotypes will not develop the condition.

Is this answer helpful? Yes No

What does this test not do?

This test does not diagnose celiac disease. Only a healthcare professional can do that.

This test does not tell you if you have celiac disease or if you will definitely develop the condition in the future.

This test does not take into account other risk factors for celiac disease, such as personal and family health history. Also, this test only looks at a limited number of genes that are part of developing the condition.

This test does not look at all possible genetic variants, genes, or haplotypes that may increase your risk of developing celiac disease.

This test does not cover other potential gluten- or wheat-related conditions.

Is this answer helpful? Yes No

Where can I learn more about celiac disease, support groups, and other resources?

You can learn more about celiac disease from the following resources:

- Celiac Disease Foundation[1]
- National Celiac Association[2]
- Beyond Celiac[3]
- Association of European Coeliac Societies[4]

If you have questions about your results or how they might affect you or your family, a genetic counselor may be able to help. Learn more about genetic counseling.

Is this answer helpful? Yes No

My report says I do not have one of the tested genetic variants, but I've been told I have the celiac disease. Why is that?

This means you do not have one of the two genetic variants we tested. These two variants are linked to the HLA-DQ2.5 and HLA-DQB haplotypes that are associated with celiac disease. However, most people with these haplotypes will not develop celiac disease. This can be caused by random test error or other factors that interfere with the test.

Most people who develop celiac disease have at least one of the two tested variants. Scientists estimate that only 2% of people with one or more copies of the HLA-DQ2.5 haplotype develop celiac disease. About 5 in 100 people develop celiac disease in the general populations.

Lifestyle and genetic factors not covered by this test also affect your chances of developing celiac disease. Learn more about other factors.

Is this answer helpful? Yes No

My report says I am not genetic at risk for celiac disease. What are some things I could do?

People without either of the tested variants have a very low chance of developing celiac disease. However, it is still possible to have the genetic variant that could not be determined in another genetic variant.

Lifestyle and other factors may also influence your risk. Learn more about other factors.

Consider talking to a healthcare professional if:

- Celiac disease runs in your family.
- You think you might have celiac disease.
- You have questions about other risk factors you may have.
- You have concerns about your results.

Is this answer helpful? Yes No

What does it mean if the result for a variant could not be determined?

This means we could not tell if you have or do not have the tested genetic variant. This can be caused by random test error or other factors that interfere with the test.

Is this answer helpful? Yes No
