Celiac Disease

Celiac disease is an autoimmune condition in which the consumption of gluten (found in wheat, barley, and rye) can result in damage to the small intestine. Celiac disease can lead to both digestive and non-digestive problems. The best-studied risk factors are common variations associated with an increased risk of developing the condition.

To view your full report, click here.

Basic, you **do not have** the two genetic variants we tested.

You are not likely at risk of developing celiac disease based on your genetics result.

0 variants detected
You have 0 of 2 risk and 0 of 2 protective variants

How To Use This Test

This test does not diagnose celiac disease or any other medical condition.

Please talk to a healthcare professional if this condition runs in your family, or if you have any concerns about your results.

Review the Genetic Health Risk tutorial
See Scientific Details
See Frequently Asked Questions

Intended Uses

- Tests for genetic tests that HLA-DQA1*I and HLA-DQB1 genes linked to the risk factor called **HLA-DQ2** haplotypes. These haplotypes are associated with celiac disease.

Limitations

- Does not test for all possible variants, genes, or haplotypes associated with celiac disease.
- Does not cover other potential protein- or wheat-related conditions.

Important Ellevations

- The variants included in this test are common in many ethnicities, but are most studied in people of **European** descent.

You **do not have** the two variants we tested associated with celiac disease.

People without the two tested variants are not likely at risk of developing celiac disease.

We ruled out the two most common variants associated with celiac disease.

See Scientific Details

Most people who develop celiac disease have at least one of the two variants tested.

Because you don't have these variants, you're more likely to develop celiac disease. Lifestyle and genetic factors can also influence the chances of developing celiac disease.

See Scientific Details

Lifestyle and other factors can also influence the chances of developing celiac disease.

Consult with a healthcare professional for more information.

Gluten

Gluten (found in wheat, barley, and rye) is the main non-genetic factor that triggers the development of celiac disease in people with increased genetic risk.

Gluten

Family history

Other conditions

See Scientific Details for more information

About Celiac Disease

Also known as: Coeliac disease, gluten sensitive enteropathy, nontropical sprue

What it develops

Celiac disease can develop anytime from infancy to adulthood. It is a chronic condition that requires a lifelong diet to maintain health.

How common is the condition?

Celiac disease affects 1 percent of all individuals. About 1 in 100 people worldwide have celiac disease.

Typical signs and symptoms

Diarrhea, gas, and bloating

Iron deficiency

Fatigue

Anemia

Headache

How it is treated

Celiac disease can be effectively treated by removing all sources of gluten from the diet. This includes foods and drinks made with wheat, barley, and rye.

Scientific Details

Celiac disease is an autoimmune condition in which the consumption of gluten (found in wheat, barley, and rye) can result in damage to the small intestine. Celiac disease can lead to both digestive and non-digestive problems. The best-studies risk factors are common variations associated with an increased risk of developing the condition.

Celiac disease is associated with the HLA-DQ2.5 and HLA-DQ8 haplotypes.

These haplotypes are associated with variants in the HLA-DQA1 and HLA-DQB1 genes.

HLA-DQA1 HLA-DQB1

Chromosome 6

The HLA gene family contains instructions for making a protein called the human leukocyte antigen (HLA) complex. The HLA-DQA1 gene provides instructions for making the HLA-DQ alpha chain protein on the surface of certain immune cells. The other half of the protein contains the beta chain protein, which is made from instructions in the HLA-DQB1 gene. It binds to the immune system to trigger the body's immune response. Certain variants in the HLA-DQA1 gene can trigger an inappropriate immune response to gluten.

Read more at: Genetics Home Reference[4]

You do not have the two genetic variants we tested.

Variants Detected View All Tested Markers

Marker Tested	Your Genotype*	Additional Information
HLA-DQ2.5 Gene: HLA-DQA1 Marker: rs2187668	C Typical copy from your other parent	T Typical copy from your other parent	• **Biological explanation** • **Typical vs. variant DNA sequence(s)** • **Percent of 23andMe customers with variant** **References:** [1], [4], [7], [16], [17], [18], [21], [22]
HLA-DQ8 Gene: HLA-DQB1 Marker: rs7454108	T Typical copy from your other parent	T Typical copy from your other parent	• **Biological explanation** • **Typical vs. variant DNA sequence(s)** • **Percent of 23andMe customers with variant** **References:** [1], [4], [7], [16], [17], [18], [21], [22]

*The most common biological variant copy was assumed from each parent. The test also cannot determine whether variants are inherited together (phased). Learn more about how we report genotypes.

23andMe always reports genotypes based on the "positive" strand of the human genome, referencing human GRCh37 (build 37) reference. Learn more about how we report genotypes using the reported strand.

Test Interpretation

Risk Estimates	Risk estimates
Risk estimates are based on clinical studies that have been conducted in European genotype and a health population.	• The HLA-DQ2.5 and HLA-DQ8 haplotypes included in this test are common in many ethnicities. However, the risk estimates in this section are based on studies in European populations.
Consider talking to a healthcare professional if you have any concerns about your results.	• Risk estimates for people of other ethnicities may be inaccurate. Because it is not known how similar the risk estimates of people with one or more copies of the HLA-DQ2.5 or HLA-DQ8 haplotypes are between ethnicities.
	• Among people who develop celiac disease, 95% have one or more copies of the HLA-DQ2.5 haplotype and 5% have one or more copies of the HLA-DQ8 haplotype. The remainder may have other haplotypes not tested by this test.
	• People without either of the two tested variants are not likely at risk of developing celiac disease.

References: [1], [4]

Other Factors

Other factors besides the variants included in this test can influence your chances of developing celiac disease.

This is not a complete list of other factors.

People with multiple risk factors may have a higher risk of developing celiac disease.

Consult a healthcare professional if these factors are a major lifestyle change.

Other Factors	References
Gluten	[1][2]
In people with a genetic predisposition for celiac disease, consuming gluten (found in wheat, barley, and rye) can trigger an immune response that leads to damage in the small intestine. This damage is the hallmark of the small intestine, and the body cannot properly absorb nutrients. As a result, people with celiac disease may develop a number of digestive and non-digestive problems. Most people with a genetic predisposition never experience any problems from eating gluten.	
Family history	[3], [5], [9]
Parents, siblings, and children of a person diagnosed with celiac disease have a higher chance of developing the condition themselves. This may primarily be explained by genetic factors, but could also be related to family members sharing similar diets. Learn more about your genetic ancestry and how it can help explain your family history.	
Other conditions	[2], [8]
People with certain health conditions are more likely to develop celiac disease. For example, people with type 1 diabetes have a 10% chance of developing celiac disease. Individuals with Williams syndrome, or an approximately 2% for people with other autoimmune conditions, such as thyroid disease. Celiac disease may also be a component in the appearance of other health conditions over the long term.	
Sex	[1, 6, 10, 24]
Some studies have shown that women are more likely to be diagnosed with celiac disease than men, but other studies did not find a difference between men and women. Scientists are still trying to figure out if there truly is a difference in risk between the two sexes.	
Other genes	[16, 17]
There are other genes and variants that have been associated with celiac disease. However, many of these variants may have only a small effect on risk.	

Test Details

Other factors besides the variants included in this test can influence your chances of developing celiac disease.

Indications for Use

The 23andMe PGS Genetic Health Risk Report for Celiac Disease is indicated for reporting of one genetic variant that is associated with celiac disease in combination with the HLA-DQ2.5 and HLA-DQ8 haplotypes. The report describes if a person has a variant linked to a haplotype that is associated with a higher risk of developing celiac disease. This report is not intended to be used as a stand-alone test of developing celiac disease. This report is meant to be used for informational purposes only.

Special Considerations

- Genetic testing for celiac disease is recommended under certain circumstances by several health professional organizations, including the American College of Gastroenterology.

Test Performance Summary

Clinical Performance

Accuracy	Sensitivity	Specificity	PPV	NPV
99.9%	99.9%	99.9%	99.9%	99.9%

Almost 99.9% of all cases of celiac disease are associated with the HLA-DQ2.5 and HLA-DQ8 haplotypes.

Analytical Performance

Accuracy was determined by comparing results from this test with results from sequencing. All test variants were detected with 99.9% confidence. This study was conducted using 1,000 genetic samples. Additional results. For more details on the analytical performance of this test, refer to the package insert.

Warnings and Limitations

- This test does not cover all variants that could cause this condition.[1]
- This test does not diagnose any health conditions.
- Share results with your healthcare professional for any medical purposes.
- If you are concerned about your results, consult with a healthcare professional.

See the Package Insert for more details on use and performance of this test.

The terms of 23andMe's Direct Genetic Test Service Agreement apply to the use of this report.

Frequently Asked Questions

Celiac disease is an autoimmune condition in which the consumption of gluten (found in wheat, barley, and rye) can result in damage to the small intestine. Celiac disease can lead to both digestive and non-digestive problems. The best-studies risk common variants associated with an increased risk of developing the condition.

Celiac Disease

What is celiac disease and how is it different from non-celiac gluten sensitivity?

Celiac disease is an autoimmune condition in which the consumption of gluten (found in wheat, barley, and rye) can result in damage to the small intestine. This damage occurs because the body's immune system mistakenly attacks the small intestine in response to gluten. Non-celiac gluten sensitivity is a term used to describe people who experience symptoms from eating gluten, but do not have celiac disease.

Other gluten- or wheat-related conditions, such as non-celiac gluten sensitivity, have also been described. Although people with these conditions have reported symptoms similar to those with celiac disease, the underlying cause is thought to be different. If you think you have a condition related to gluten consumption, talk to your doctor. If you have a family history of celiac disease, talking to a healthcare provider may help determine if your testing is appropriate.

You can learn more about celiac disease from the following resources:

- Celiac Disease Foundation[1]
- National Celiac Association[2]
- Beyond Celiac[3]
- Association of European Coeliac Societies[4]

Is this answer helpful?

Yes No

What does this test do?

This test looks for two specific genetic variants, one in the HLA-DQA1 gene and one in the HLA-DQB1 gene. These variants are part of the HLA-DQ2.5 and HLA-DQ8 haplotypes. These two haplotypes are associated with celiac disease.

People with the HLA-DQ2.5 and HLA-DQ8 haplotypes are more likely to develop celiac disease. However, most people with these haplotypes will not develop the condition.

This test does not include all possible genetic variants, genes, or haplotypes that may increase your risk of developing celiac disease.

Is this answer helpful?

Yes No

What does this test not do?

This test does not diagnose celiac disease. Only a healthcare professional can do that.

This test does not rule out if you have celiac disease or if you will develop the condition in the future.

This test does not rule out the presence of risk factors for celiac disease, such as personal and family health history. Thus, this test cannot provide a complete assessment of your risk of developing the condition.

This test does not include all possible genetic variants, genes, or haplotypes that may increase your risk of developing celiac disease.

This test does not cover other potential gluten- or wheat-related conditions.

Is this answer helpful?

Yes No

Where can I learn more about celiac disease, support groups, and other resources?

You can learn more about celiac disease from the following resources:

- Celiac Disease Foundation[1]
- National Celiac Association[2]
- Beyond Celiac[3]
- Association of European Coeliac Societies[4]

If you have questions about your results or how they might affect you or your family, a genetic counselor may be able to help. Learn more about genetic counseling.

Is this answer helpful?

Yes No

My report says I am a carrier. What does this mean?

This means we called out two common variants linked to the HLA-DQ2.5 and HLA-DQ8 haplotypes that are associated with celiac disease.

About 1 in 100 people develop celiac disease in the general population. Most people who develop celiac disease have at least one of the two tested variants. Because you don't have these variants, your chances of developing celiac disease are lower.

Lifestyle and other genetic factors can also influence your chances of developing celiac disease. Learn more about other factors.

Is this answer helpful?

Yes No

My report says I have variants associated. What are some things I could do?

People without either of the tested variants have a very low chance of developing celiac disease.

Consider talking to a healthcare professional if:

- Celiac disease runs in your family.
- You think you might have celiac disease.
- You have questions about other risk factors you may have.

Is this answer helpful?

Yes No
